The issue is that when the first gear slides along its gear and the second gear stops the slide, there is a significant back and forth movement. I am trying to apply a lateral force to prevent this. I am using a solenoid to apply an axial force, but the direction of the force is changing direction a few times during a slide. I am suspecting that the rotation of the gears is causing this issue. I am looking for solutions that may be looking to fix this problem. Solutions such as using a larger gear ratio or a larger diameter drive gear may not be available. A: The back-and-forth movement is due to the side forces acting on the sliding gear. You can reduce this by using a thicker gear. If you use a thick gear with a thinner gear in the back, you can insert a wedge in the back (or find another way to compensate for the back force, perhaps with a steel piece). You can also use different friction products for the different gears. (But remember to use the same kind of grease on all parts that contact each other, in c6a93da74d
