

[Download](#)

it is possible to create not only models of structural elements of buildings, but also fixed structures such as bridges, tunnels, and tunnels. it is possible to use the adequate displacement of reinforced concrete or a rubber system with deformable reinforcement. the evaluation of the structural behavior of a structural element or building in a three-dimensional model is far more practical, depending on the quality of the input data. in addition, the size and the structure of the models of building components are much more accurate than other programs of 3d calculation. in this way, building structure design can be carried out in the shortest time possible, allowing you to focus on other aspects of the project. the results obtained can be shared with the client, who will appreciate the work and approval of the technical staff and the evaluation of the results are based on the risks of the structural design. this model can be used to the selection and design of architectural building, as well as to the optimization and analysis of the structure by small or large scale. the possibility of the creation of a 3d model of architecture is a big advantage, since this permits optimization of the different components of the structure. it is possible to make the use of the load types permitted by the expansion of the structure, or to use them from any civil structure. the properties of the reinforcement can also be changed through the use of the expansion layer, selecting the material that best responds to the type of load that the structure imposes. no new element of architecture is required, since it is possible to modify any existing structure, in terms of expansion layer, as well as properties of the material and properties of the reinforcement. the time that you save in the calculation, permits you to design the whole structure in much fewer hours of calculation. the use of two or three dimensions allows you to visualize the project, once the cost is determined, before the construction site.
